| Package | star-wahba |
| Version | 0.1.0 |
| Capability | star.attitude.wahba |
| Maturity | Released & Verified (RELEASED) |
| Python | ⩾3.9 |
| Source commit | dc09f61 |
| Source | https://github.com/Andrea07072000/S.T.A.R.-/tree/main/packages/star_wahba |

# 2. Licence and obligations

Apache License 2.0. You may use, copy, modify and distribute it, also commercially, and you receive a patent licence from the contributors. When you redistribute it: keep the LICENSE file and the copyright notices (and a NOTICE file, if a future version adds one), and state in modified files that you changed them. You may not use the S.T.A.R. name to endorse your product.

# 3. What it needs at run time

Nothing beyond the Python standard library: it works offline.

# 4. Integrity

SHA-256 fingerprints of the files published on this website. Check a downloaded file with:

```
python -c "import hashlib,sys;print(hashlib.sha256(open(sys.argv[1],'rb').read()).hexdigest())" star_wahba-0.1.0-py3-none-any.whl
```

| FILE | SHA-256 |

# 5. What it does, and its limits

Attitude from vector observations: TRIAD for two directions and Davenport's q-method (Wahba's problem) for 2 to 1000 weighted directions, with the eigenproblem solved by Jacobi rotations in the standard library; conversion to the attitude matrix and the Wahba loss; within 7e-15 of SciPy's SVD solution and 5e-16 of ahrs TRIAD on 401 attitudes.

A single-frame estimate: no filtering over time, no gyro, no covariance of the estimate, no bias estimation, no QUEST or ESOQ variants (they solve the same problem faster; this one favours robustness over speed). TRIAD and the q-method give different answers on noisy data by design: TRIAD trusts the first observation entirely. Nearly parallel observations are accepted down to 1e-12 and give an attitude that is very sensitive to noise about their common direction: the functions do not warn about it. No published numerical example is reproduced: the references (Wahba 1965, Black 1964, Davenport 1968, Markley and Crassidis) are cited for the method.

- `triad(r1, r2, b1, b2)` returns the attitude matrix A (reference to body, b = A r) that matches the first pair exactly; `q_method(refs, bodies, weights)` returns the unit quaternion (w, x, y, z), w >= 0, that minimises Wahba's loss; `rotation_matrix(q)` converts it to A; `wahba_loss` evaluates 0.5 Σ w |b - A r|² with the weights normalised to sum 1.
- TRIAD by two orthonormal triads; the q-method by the eigenvector of the largest eigenvalue of Davenport's K matrix, found with Jacobi rotations. Vectors need not be unit: only their directions are used.
- Measured on 401 attitudes with 2 to 8 weighted directions, half of them with 0.01 rad of noise: the q-method agrees with the singular-value solution of SciPy within 7e-15 in every element of the matrix, TRIAD with the TRIAD of ahrs within 5e-16.
- Every function returns floats or raises `ValueError`: vectors that are not three finite numbers or are zero, fewer than 2 or more than 1000 pairs, weights that are not positive, directions that do

not fix an attitude (parallel), a zero quaternion.

## 6. Export, use and certification

The package is published and freely available. That usually takes software out of export-control lists, but not every use of it: read the page on space activities and export control before using it in a controlled programme. It is not certified or qualified for flight; the evidence describes what was tested and how.

## 7. Citation and bill of materials

```
